

FTS Real Time Project: Understanding Risk and Return

Question: How are risk and return typically measured?

- When you invest in stocks or bonds or other securities, you have to decide how much you want to invest in each security. This decision requires you to estimate how well you think each security will perform, and how risky each security is. Beyond that, if you invest in more than one security, you may have a reduction of risk due to diversification. In this project, we explore common measures of risk and return, applied to stocks.
 - You can conduct this project with any of the equity cases. In our description, we will use the FTS 30 Stock Case.
 - If you are not familiar with the FTS Real Time Client, we suggest you work through the <u>"How Securities are Traded</u>" project.

Definitions

Let $E(r_i)$ denote the expected return from stock i. This is measured annually, so $E(r_i)=10\%$ means you expect the stock to return 10% over the year. For example, suppose a stock's current price is 50 and the expected return is 10%. Then, we expect that in one year, the stock price will be 55. It does not have to be 55, it could be more or less, but the expected value of prices in the future is 55.

There are many ways to estimate the expected return; stock analysts use techniques involving historical data, fundamental analysis, and scenario analysis. Values based on the CAPM are provided by the FTS Real Time Client, though you can override them with your own estimates using the "Parameters" menu item.

Modern portfolio theory uses the standard deviation of returns (also called *volatility*) as a measure of risk (or equivalently, the variance).

Expectations versus Realizations

Both the expected return and the volatility reflect expectations about the future. That's natural because when you make the decision to invest, you don't know what will happen in the future and so the decision must be based on estimates of what you think will happen.

What actually happens may or may not correspond to your expectations. For example, if the stock price is 60 at the end of the year instead of 55 as expected, you would have a realized return of 20%. Of course, that is only one observation, and one observation cannot confirm that our expectations were correct. To measure if our expectations were realized, we therefore calculate what happens over a number of observations and see whether on average, we were correct.

Operationally, this means that we calculate the return on each stock over a number of periods (e.g. daily) and then calculate the realized return, the average realized return and the volatility of the return.

Let r_{it} be the realized return on stock i between time t-1 and t, calculated as

$$r_{it} = \frac{P_{i,t} - P_{i,t-1}}{P_{i,t-1}}$$

Over T periods, we calculate the average of the individual stock returns and the standard deviation of these returns and compare them to the expectations.

Project

- 1. To start, buy two stocks. Invest an equal dollar amount in each. For example, if you start with \$1m, you could invest \$495,000 in each stock.
 - Why 495,000 and not 500,000? See below.
 - You have to calculate the number of shares of each stock. This is done as follows: if P is the price of the stock, and you want to invest \$495,000, then the number of shares is 495000/P. If this is not a round number, you have to round it down or up.
 - You may not be able to trade at exactly the price at which you calculated the number of shares because stock prices can change fairly quickly. Also, you buy at the ask price, which is typically higher than the last traded price. So we recommend investing a slightly smaller amount, e.g. \$495,000, in each stock, so you don't run out of money.
 - So if P is the stock price, the number of shares will be rounded to 495000/P.
 - If the number of shares is large, you may have to trade several times; this is illustrated below.
- 2. Choose the stocks to have different volatilities and expected returns. You can see the volatilities and expected returns in the Index Model (CAPM) analytics, shown below
 - We have circled the expected return and volatility estimates as well as the Edit menu item of the analytics display. We will select 3M and AT&T as our stocks.

- 3. At the time you place your trades, keep a record of the expected return and volatility of the stocks you picked; the easiest way to do this is to export the analytics into Excel and save the spreadsheet; this can be done by selecting "Export to Excel" from the Edit menu of the analytics display, as shown above. You can also copy and paste the information from the same edit menu, as we have done.
- 4. When we placed our trades, we received the following trade confirmations:

| S Trade Confirmations/ | Session History |
|---|-----------------|
| <u>F</u> ile <u>E</u> dit <u>O</u> ptions | |
| Time | Activity |
| 11/13/2013 9:47:04 AM | CASHBUY BY |
| 11/13/2013 9:47:52 AM | CASHBUY BY |
| 11/13/2013 9:48:04 AM | CASHBUY BY |
| • | |

And your position summary shows that we have invested approximately \$495,000 in each of the stocks.

- 5. After a few days (at least 5), calculate the realized average return and the volatility of each stock and your portfolio, as follows.
 - First, download your history from the Reports menu at the top:

| 💲 FT | 'S Real Ti | me Trader: | Client. Versio | on 4.0.0.4 | | - | _ | | |

6. Remove weekends and holidays

- Why: because markets are closed on those days and so the value of the position will not change, i.e. you will have a zero return on those days, which will bias your results.
 - During our exercise, the US Thanksgiving holiday was on November 28, as shown:

7. Now, we have to calculate returns. The return on a stock is calculated as:

$$r_{it} = \frac{P_{i,t} - P_{i,t-1}}{P_{i,t-1}}$$

Here, Pi,t is the price of stock i on date t.

- Calculate the returns in Excel. The first day on which we have a return is 11/14/2013, i.e. the second day. The value of our position in 3M on that day is 501119.2, up from 496486 on 11/13/2013.
 - The return is (501119.2-496486)/496486 = 0.00933
 - Side note: at the time we bought 3M on 11/13/2013, the value was 494980. The value at the end of the day was 496486, so the stock gained value within the day. The calculations here are all based on end-of-day values.

- The formula in the spreadsheet is =(C3-C2)/C2
- The formula for the first return for AT&T is =(D3-D2)/D2
- The formula's for all the returns are shown in this picture:
